Compression Therapy for Foot Wounds

Steven Miller, D.P.M.

Wounds 17(10): 278-281, 2005

Interstitial edema can impair wound healing. Compression is a well-documented, effective method to reduce interstitial edema associated with venous leg ulcers. However, there are few reports of its effectiveness in the management of foot wounds. The author presents 2 cases where multilayer compression bandages were instrumental in the treatment of foot wounds.
